Present Day, Present Time: AI Exposure and Labor Market Risk

March 24, 2026

Building on Trade Theory

- **Task-based production:** firms combine a *continuum of tasks*, not just labor and capital
  - Tasks differ in how easily they can be delegated to a cheaper alternative
- **Grossman & Rossi-Hansberg (2008) — "Offshoring Tasks"**
- **Ottaviano, Peri & Wright (2013)— "Who are affected"**
- **Why does this apply to AI?**
  - AI = a technology that can perform certain tasks at low cost
  - **"offshoring" (outsourcing) tasks to Claudeland, GPTopia, Geminia...**
  - Workers whose tasks AI can undercut face the same wage pressure as offshored workers

Model Setup

- **Tasks** indexed $i \in [0, 1]$ by AI susceptibility
  - Low i: routine cognitive (drafting, coding, data entry) — easy for AI
  - High i: human expertise — hard for AI *currently*
- **CES Production**:

$$Y = \left[\int_0^1 y(i)^{\frac{\sigma-1}{\sigma}} \, di \right]^{\frac{\sigma}{\sigma-1}}$$

- **Workers:** type i^* specializes in task i^*; supply of task i is $f(i)$ (fixed)
- **AI cost** of task i: $c^{\mathrm{AI}}(i) = \tau \cdot e^{\alpha i}$
  - Lower τ = more capable AI
  - $e^{\alpha i}$ ensures complex tasks remain expensive for AI
- Competitive firms; output price P_Y fixed (small open economy)

Pre-AI Equilibrium: Derivation

Firm cost minimization gives task demand:

$$y^d(i) \;=\; Y \cdot \left(\frac{P_Y}{p_0(i)}\right)^{\sigma}$$

Higher task price $\rightarrow$ firm demands less of that task (substitution).

Market clearing $\big(y^d(i) = f(i)\big)$ pins down equilibrium task price:

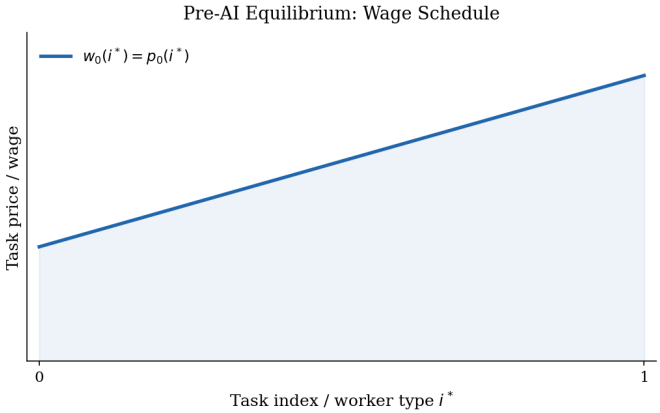
$$\boxed{p_0(i) \;=\; P_Y \cdot \left(\frac{Y}{f(i)}\right)^{1/\sigma}}$$

- Scarce worker types (low $f(i)$) command higher task prices
- Abundant worker types (high $f(i)$) earn less

Pre-AI Equilibrium: Wage Schedule

Step 3 — Under full specialization, each worker earns their task price:

$$w_0(i^*) \;=\; p_0(i^*)$$



- Each worker type i^* earns the competitive price of their task
- Higher-i^* workers earn more (their tasks are harder to replace)

Note: upward slope is for illustration only — model imposes no shape restriction on p_0

Immediate Effects of the AI Shock

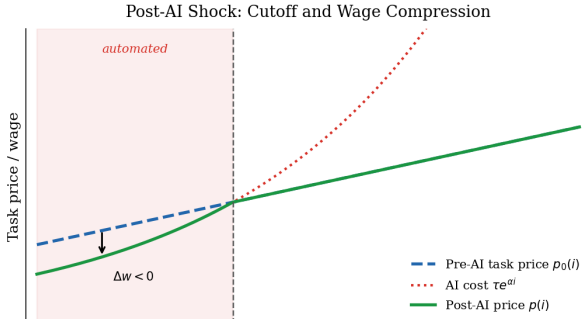
Key framing: we hold $Y = Y_0$ fixed — analyzing the *immediate* impact before the economy has time to adjust

This isolates the **substitution channel** only. Longer-run channels set aside:

- **Augmentation** — AI complements some workers, raising productivity over time
- **Output expansion** — cheaper production eventually raises Y, benefiting non-automated workers

Immediate task price once AI enters:

$$p(i) = \min\big(p_0(i),\ \tau e^{\alpha i}\big) \qquad \Rightarrow \qquad \text{cutoff } I^* :\ \tau e^{\alpha I^*} = p_0(I^*)$$



- $i < I^*$: AI immediately undercuts → wage compression

$$\Delta w = \tau e^{\alpha i^*} - p_0(i^*) < 0$$

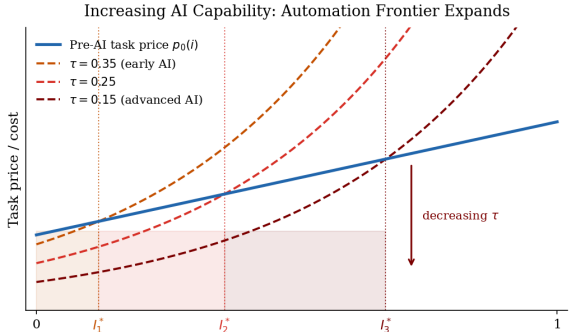
- $i \geq I^*$: no direct price pressure in the short run
- Compressed wage $<$ reservation wage →

What Determines the Cutoff I^*?

As AI improves ($\tau \downarrow$), I^* rises

$$\frac{\partial I^*}{\partial \tau} < 0$$

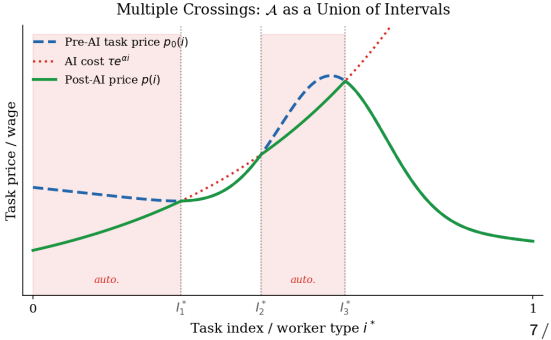
The automation frontier expands toward more complex tasks.



What if $p_0(i)$ is non-monotone?

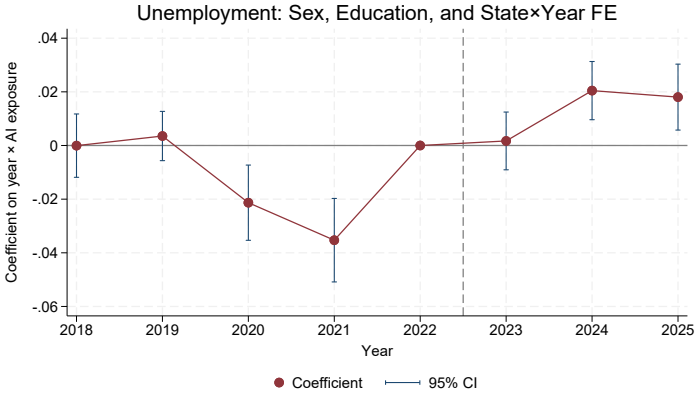
Cutoff may not be unique $\rightarrow$ automated set is a union of intervals:

$$\mathcal{A} = [0, I_1^*] \cup [I_2^*, I_3^*] \cup \cdots$$



Do We See This in the Data?

Unemployment × AI Exposure (CPS-ASEC, 2018–2025)



- Compare high vs. low AI-exposure workers, before vs. after ChatGPT (2022)
- Year 2022 = baseline
- **Post-2022:** high-exposure workers show rising unemployment
- Consistent with the model: workers below I^* face displacement

Thank you!

Questions welcome.
